

1. General description

The SSL5511T is an offline dimmable controller IC, intended to drive dimmable LEDs in general lighting applications, like remote-controlled luminaires and smart lamps.

The main benefits of this IC include:

- Dim level control with either an analog or a digital control input
- Selectable modes for high power factor or low ripple, allowing a wide LED power range
- Large dimming range
- Single stage topology for small PCB footprint
- Ease of design-in
- Integrated start-up JFET
- Low electronic Bill Of Material (BOM)
- Various converter topologies supported

The IC drives an external switch for easy power scaling. It has been designed to start up directly from the High-Voltage (HV) supply by an internal high-voltage current source. Flyback, buck and buck-boost circuit topologies are supported. Primary side sensing provides accurate output current control.

The IC can detect analog signals (according to IEC60929 annex E) or digital control signals and translate them to a continuous LED current in multiple ways. It can operate in three switching modes at two switching frequency ranges. It offers tradeoffs between the output current ripple, the mains current Total Harmonic Distortion (THD) and the application size. The IC incorporates all required protection features.

2. Features and benefits

- LED controller IC for driving strings of LEDs or high-voltage LEDs from rectified mains
- High-efficiency switch mode buck, flyback or buck-boost controller driving an external power FET
 - Two maximum switching frequencies for highest efficiency or smallest application size
 - Zero current switching at switch turn-on
 - Zero voltage or valley switching at switch turn-on
 - Selectable low THD or low LED current ripple modes
- Analog IEC60929 input or digital control input for dimming
- Continuous (analog) regulation of LED current in both the dimming control modes
- Dim curve selection based on the control input type
- No binning on LED forward voltage required
- LED current accuracy within ±4 % across variations in components and conditions
- Built-in Protections:
 - UnderVoltage LockOut (UVLO)
 - Leading Edge Blanking (LEB)
 - OverCurrent Protection (OCP)
 - Internal OverTemperature Protection (OTP)
 - Brownout protection
 - Output Short Protection (OSP)
 - Output open OverVoltage Protection (OVP)
 - Mains synchronization loss protection
- Low component count LED driver solution
- Compatible with wall switches with built-in indication light during standby(
- IC lifetime matches or surpasses LED lamp lifetime

3. Applications

Compact mains connected, remote-controlled LED lamps with accurate, dimmable current output for single or universal mains voltages, including 100 V (AC), 120 V (AC) and 230 V (AC). External components determine the power level. The power level ranges from 4 W to over 25 W. Applications fit in common form factors like PAR, GU10, A19, and the candle form factor.

Functional description 8.

8.1 **Pin functionality**

8.1.1 Pin RMAINS

The RMAINS pin takes in a current representing the rectified mains voltage via the external RMAINS resistors. The low ohmic input results in current always flowing, causing the voltage on the RMAINS pin to remain below the maximum V_{i(RMAINS)} at any time. The information about the mains voltage is used to shape the output current waveform in LTHD modes. It is also used for internal timing synchronizations, making it essential for the low-ripple applications. Some filtering may be required outside the IC to eliminate incoming noise.

If the pin does not receive a rectified mains signal, the mains synchronization loss protection is triggered.

8.1.2 Pin VCC

At power-up, the VCC pin and its capacitor are charged using the internal HV current source from the DRAIN pin. Once V_{CC} has reached V_{CC(startup)}, switching starts and V_{CC} supply is generated from the auxiliary winding. If V_{CC} exceeds $V_{ovp(VCC)}$ due to, for example, a disconnected output, OVP is triggered. If V_{CC} drops to V_{CC(low)}, the internal HV current source is enabled. If V_{CC} drops to below V_{CC(stop)}, UVLO protection is triggered.

Do not use the VCC pin to power additional circuitry outside the IC because no additional current budget is guaranteed. An additional V_{CC} load can affect product performance.

To support wall switches that include an indicator light, a predetermined current (I_{CC}) is pulled from the supply during a limited window of the VCC voltage (see condition 2 of I_{CC} in Table 7).

8.1.3 Pin DIM

The DIM pin is the dimming level control pin. It also acts as the on/off control pin. It accepts both an analog voltage signal and a digital control signal as input. The type of input signal is automatically detected and the input is then translated into a target output current level (see Section 8.2.6).

8.1.4 Pin ISNS

The ISNS pin senses the voltage across the sense resistor, R_{SNS}, generated by the inductor current flowing through the external MOSFET and this resistor (see Figure 3).

Optionally, a mode definition resistor is present between the pin and the current sense resistor. At start-up, the mode resistor is measured using a current which is sourced out of the pin.

8.1.5 Pin PWRDRV

The SSL5511T is equipped with a driver that controls an external MOSFET. The voltage on the driver output pin is increased towards the maximum $V_{o(PWRDRV)}$ to open the switch during the first cycle (t0 to t1; see Figure 4). It is pulled to ground from the start of the secondary stroke until the next cycle starts (t1 to t00).

8.1.6 Pin DRAIN

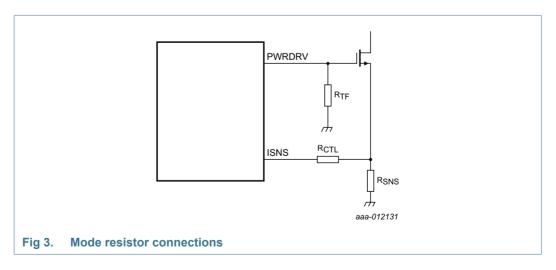

The DRAIN pin is used to derive energy to charge the VCC pin at start-up and after switching is stopped because of a triggered protection. The signal at the DRAIN pin is also used to detect demagnetization and to determine the valley of the ringing voltage for starting the primary stroke.

8.2 Converter operation

8.2.1 Available modes

The SSL5511T incorporates various built-in operation modes which can be selected in the application using a maximum of two external resistors. At start-up, the value of these resistors is detected and the corresponding operation mode is set.

The mode resistor at the PWRDRV (R_{TF}) is connected to ground. The mode resistor at the ISNS pin (R_{CTL})is connected between the pin and the external MOSFET source (see Figure 3).

Table 4 Available modes

8.2.2 Switching scheme

The converter in the SSL5511T is a Discontinuous Conduction Mode (DCM), peak current controlled system. When the output current control system requires a new switching cycle and the inductor current is zero, the external MOSFET is turned on at the next detected valley (see Section 8.2.3). The inductor current increases until a maximum, defined by the regulation loop, is reached and the MOSFET is switched off. The inductor current reduces again. When the inductor current reaches zero, it is detected at the DRAIN pin. The detection enables the control system to regulate to an accurate average value of the LED current.

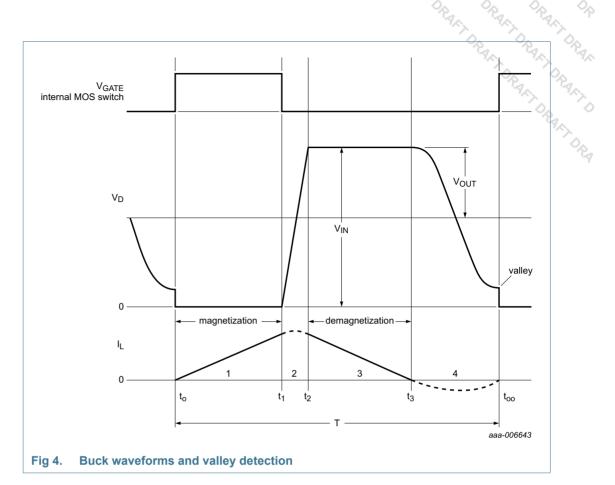

The maximum switching frequency can be set at two rates (see Section 8.2.1).

Three options are available which determine how the controller adjusts the maximum inductor peak current over the mains cycle. The result is either an optimal input current shape (optimized power factor and THD), a minimal LED current ripple, or an intermediate solution (eco-LTHD mode).

8.2.3 Valley detection

A new cycle is started when the primary switch is switched on (see Figure 4). At a certain time (t1), the switch is turned off and the secondary stroke starts. After the secondary stroke (t3), the drain voltage shows oscillation or ringing. Circuitry at the DRAIN pin senses when the voltage on the drain of the switch has reached its lowest value (valley) during each oscillation. When the control loop requires the next cycle, it is started the next time a valley occurs. As a result, the capacitive switching losses reduce significantly. For successful valley detection, the frequency and amplitude of the drain voltage ringing must cause the slope of the ringing voltage to exceed the detection limit $(\Delta V/\Delta t)_{vrec}$ for at least t_{d(vrec-swon)}.

Greenchip controller for LED lighting with DIM pin

8.2.4 Output current settings

The IC regulates the output LED current with great accuracy over line, load and component variations. The user can set the full-scale (100 %) value of the LED current. Choose a current sense resistor value according to Equation 1:

$$I_{LED} = \frac{V_{reg}}{R_{SNS}} \times N \tag{1}$$

Where:

- V_{reg} is the set point of the internal regulation loop: 117 mV for LTHD buck-boost/flyback, 234 mV for LTHD buck and low ripple buck-boost/flyback, and 469 mV for low-ripple buck
- R_{SNS} is the sense resistor on pin ISNS (see Figure 3)
- N is the transformer ratio

The IC regulates the output current by controlling the current sense threshold voltage $V_{th(ISNS)}$, the number of switching cycles per (half-)mains period, and, if necessary, the switching frequency, depending on the mode of operation.

8.2.5 Preventing Continuous Conduction Mode (CCM)

To enable application design without having to include margins to ensure DCM operation, a CCM-prevention feature has been built in. The IC monitors the time gap between the end of the secondary stroke and the start of the next cycle. If this time becomes shorter than a predetermined idle time of about 1.8 μ s, the controller reduces the switching frequency.

8.2.6 Dimming support

The SSL5511T accepts one of two different types of control signals on the DIM pin, either an analog voltage signal or a digital control signal. The type of the dimming control is detected during start-up. If digital switching occurs on the DIM pin, or if a voltage above the analog dimming input range ($V_{ctrl(A)DIM}$) is present on the pin, digital dimming control is detected. If a voltage within the analog range ($V_{ctrl(A)DIM}$) is present on the pin, then analog dimming control is detected. If the input remains low (below the analog dimming range), the target output current level is set to zero, and standby mode is entered. Dim mode selection is then postponed until one of the above detection conditions is met. Once the dimming type is detected, it is set fixed until power-down. During operation in either analog or digital dimming mode, the measurement of the DIM pin is done once in every full mains cycle. For both dimming control types, the output current regulation remains analog.

Analog Input Dimming Control (AIDC):

In this mode, an input voltage within the analog range ($V_{ctrl(A)DIM}$) is accepted on the DIM pin and translated to a target output current level. Figure 5 shows the plotting of the dimming percentage of the output current against the input voltage. The smooth tail of the curve matches human eye light sensitivity. The minimum output current level as a ratio of the full-scale current is I_{LEDIoW}/I_{LED100} . If the input voltage drops to below the analog range by more than the built-in hysteresis ($V_{hys(low)DIM}$), the output current is set to zero. The IC enters standby mode. Some filtering may be required outside the IC to eliminate incoming noise.

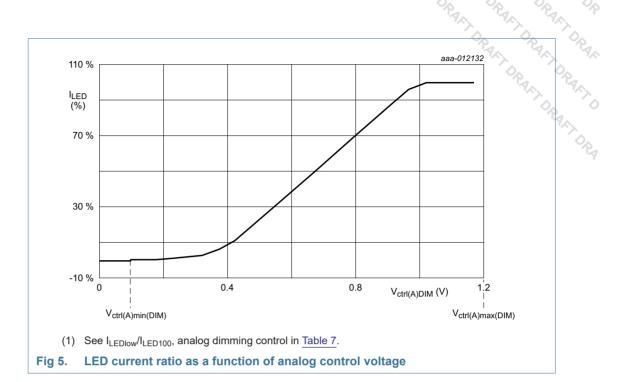

• Digital Input Dimming Control (DIDC):

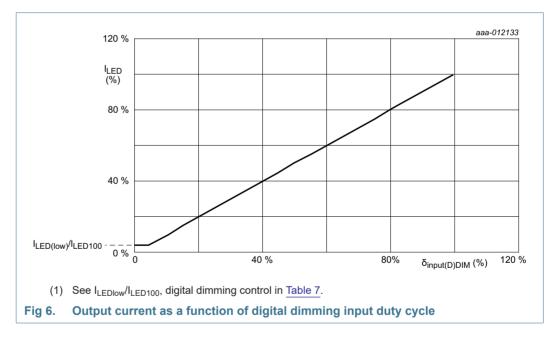

A digital signal of a frequency within the range $f_{i(DIM)}$, and levels satisfying the thresholds $V_{th(L)DIM}$ and $V_{th(H)DIM}$ are accepted and translated to a target LED current level. The dimming percentage of the output current equals the duty cycle of the input signal (expressed as a percentage; see Figure 6). The minimum output current level as a ratio of the full-scale current is I_{LEDIoW}/I_{LED100} . If the input signal is low for longer than $t_{det(stb)DIM}$ in the measurement window, the output current is set to zero. The IC enters standby mode.

8.3 Protections

The IC incorporates the following protections:

- UnderVoltage LockOut (UVLO
- OverCurrent Protection (OCP)
- Brownout Protection
- Output Short Protection (OSP)
- Output open OverVoltage Protection (OVP)
- Internal OverTemperature Protection (OTP)
- Mains synchronization loss protection
- Leading Edge Blanking (LEB)

Output open OVP is a latched protection. Power-off cycling is required to exit the latched state. All other protections are not latched and lead to a safe restart of the converter.

8.3.1 UnderVoltage LockOut (UVLO)

When the voltage on the VCC pin drops to below the value of $V_{CC(stop)}$, the IC stops switching. The internal HV current source is enabled. Once V_{CC} has increased to $V_{CC(startup)}$, the IC restarts a minimum of 1 s back-off time.

8.3.2 OverCurrent Protection (OCP)

The SSL5511T contains a highly accurate peak current detector. It triggers when the voltage at pin ISNS reaches $V_{th(ISNS)}$. The circuit is activated after the leading edge blanking time (t_{leb}). There is a propagation delay between the peak current detection and the switch actually switching off. Due to this delay, the actual peak current is slightly higher than the peak current level set by the current sense resistor. The control loop compensates for this difference ensuring output current accuracy.

8.3.3 Brownout protection

The brownout protection is designed to limit the switch-on time in case of low input voltage. Because of the built-in peak current control, the input current otherwise slowly increases while no power is transferred to the output in a flyback configuration. The SSL5511T includes a maximum on-time of the switch $t_{on(high)}$.

8.3.4 Output short protection (OSP)

During the secondary stroke (switch-off time), if a valley is not detected within the off-time limit ($t_{off(high)}$), the output voltage is typically less than the minimum limit allowed in the application. This condition can occur either during start-up or due to a short. A timer is started when $t_{off(high)}$ is detected. It is only stopped if a valid valley-detection occurs in one of the subsequent cycles. If no valley is detected for $t_{det(sc)}$, it is concluded that a real short-circuit exists and not a temporary start-up situation. The IC enters standby mode and tries to restart after a minimum of 9 s back-off time.

8.3.5 Output open OverVoltage Protection (OVP)

The result of an output open situation is that no power is delivered to the output, causing V_{CC} to exceed $V_{CC(max)}$. Upon detection of this event, the IC enters the standby mode. As long as mains voltage is present, the IC does not restart.

8.3.6 Internal OverTemperature Protection (OTP)

When the internal OTP function is triggered, the converter stops operating. This function is triggered at $T_{th(act)otp}$. The Overtemperature protection is an auto-restart protection. The IC restarts when the IC temperature drops to below $T_{th(rel)otp}$.

8.3.7 Mains synchronization loss protection

When the input current at the RMAINS pin fails to cross the "zero crossing detection" value of $I_{i(RMAINS)}$, no mains cycles are detected. If this situation persists for a time $t_{d(mld)}$, the IC stops switching. Once a valid mains signal is available again, the IC restarts.

8.3.8 Leading Edge Blanking (LEB)

A blanking time is implemented after switch-on to prevent premature detection of inductor peak current. At the opening of the MOSFET switch, a short current spike can occur because of the capacitive discharge of voltage over the drain and source. During the leading edge blanking time (t_{leb}), detection is disabled. So spikes are disregarded.
