

SSL4101T

GreenChip III+ SMPS control IC

Rev. 1 — 21 April 2011

Product data sheet

1. General description

The GreenChip III+ is the third generation of green Switched Mode Power Supply (SMPS) controller ICs. The SSL4101T combines a controller for Power Factor Correction (PFC) and a flyback controller. Its high level of integration allows the design of a cost-effective LED lighting application power supply with a very low number of external components.

The special built-in green functions provide high efficiency at all power levels. This applies to quasi-resonant operation at high power levels, quasi-resonant operation with valley skipping, as well as to reduced frequency operation at lower power levels. At low power levels, the PFC switches off to maintain high efficiency.

During low power conditions, the flyback controller switches to frequency reduction mode and limits the peak current to 25 % of its maximum value. This will ensure high efficiency at low power and good standby power performance while minimizing audible noise from the transformer.

The SSL4101T is a MultiChip Module, (MCM), containing two chips. The proprietary high voltage BCD800 process which makes direct start-up possible from the rectified universal mains voltage in an effective and green way. The second low voltage Sillicon On Insulator (SIO) is used for accurate, high speed protection functions and control.

The SSL4101T enables extremely efficient and reliable LED lighting application power supplies with power requirements from 10 W to 300 W, to be designed easily and with a minimum number of external components.

The new SSL4101T allows a typical 150 W LED lighting application power supply (universal input, 48 V (DC) output, TEA1761T on the secondary side for Synchronous Rectification) to achieve the following performances at full load:

- 120 V (AC): 92 % efficiency, 0.998 PF, 5.8 % THD, < 190 mW standby power
- 277 V (AC): 94 % efficiency, 0.978 PF, 9 % THD, < 350 mW standby power

1.1 Industry standard THD, low standby input power and high-efficiency

The SSL4101T enables LED lighting application power supplies to achieve the industry standard of < 20 % THD for the input current at full load and all nominal input voltages: 100 V (AC), 120 V (AC), 230 V (AC), 240 V (AC) and 277 V (AC).

- Extremely low input power in Standby mode eliminates the need for an additional housekeeping power supply to power the lighting controllers/dimmers.

- Using SSL4101T, a low power controller (< 50 mW) can be driven directly by the LED lighting application power supply's output while maintaining the input power in Standby mode below the maximum of 0.5 W.
- Extremely high-efficiency can be achieved in LED lighting application power supplies using the SSL4101T (between 92 % to 94 %). This enables the power supply to operate reliably in enclosed spaces with very little cooling (which is typical for SSL applications).

2. Features and benefits

2.1 Distinctive features

- Integrated PFC and flyback controller.
- True universal mains supply operation: 70 V (AC) to 305 V (AC).
- High level of integration, resulting in a very low external component count and a cost-effective design.

2.2 Green features

- On-chip start-up current source.

2.3 PFC green features

- Valley/zero voltage switching for minimum switching losses (NXP Semiconductors patented).
- Frequency limitation to reduce switching losses.
- PFC is switched off when a low load is detected at the flyback output.

2.4 Flyback green features

- Valley switching for minimum switching losses (NXP Semiconductors patented).
- Frequency reduction with fixed minimum peak current at low power operation to maintain high efficiency at low output power levels.

2.5 Protection features

- Safe restart mode for system fault conditions.
- Continuous mode protection by means of demagnetization detection for both converters (NXP Semiconductors patented).
- UnderVoltage Protection (UVP) (foldback during overload).
- Accurate OverVoltage Protection (OVP) for both converters (adjustable for flyback converter).
- Open control loop protection for both converters. The open loop protection on the flyback converter is safe restart.
- IC OverTemperature Protection (OTP).
- Low and adjustable OverCurrent Protection (OCP) trip level for both converters.
- General purpose input for latched protection, e.g. to be used for system OverTemperature Protection (OTP).

3. Applications

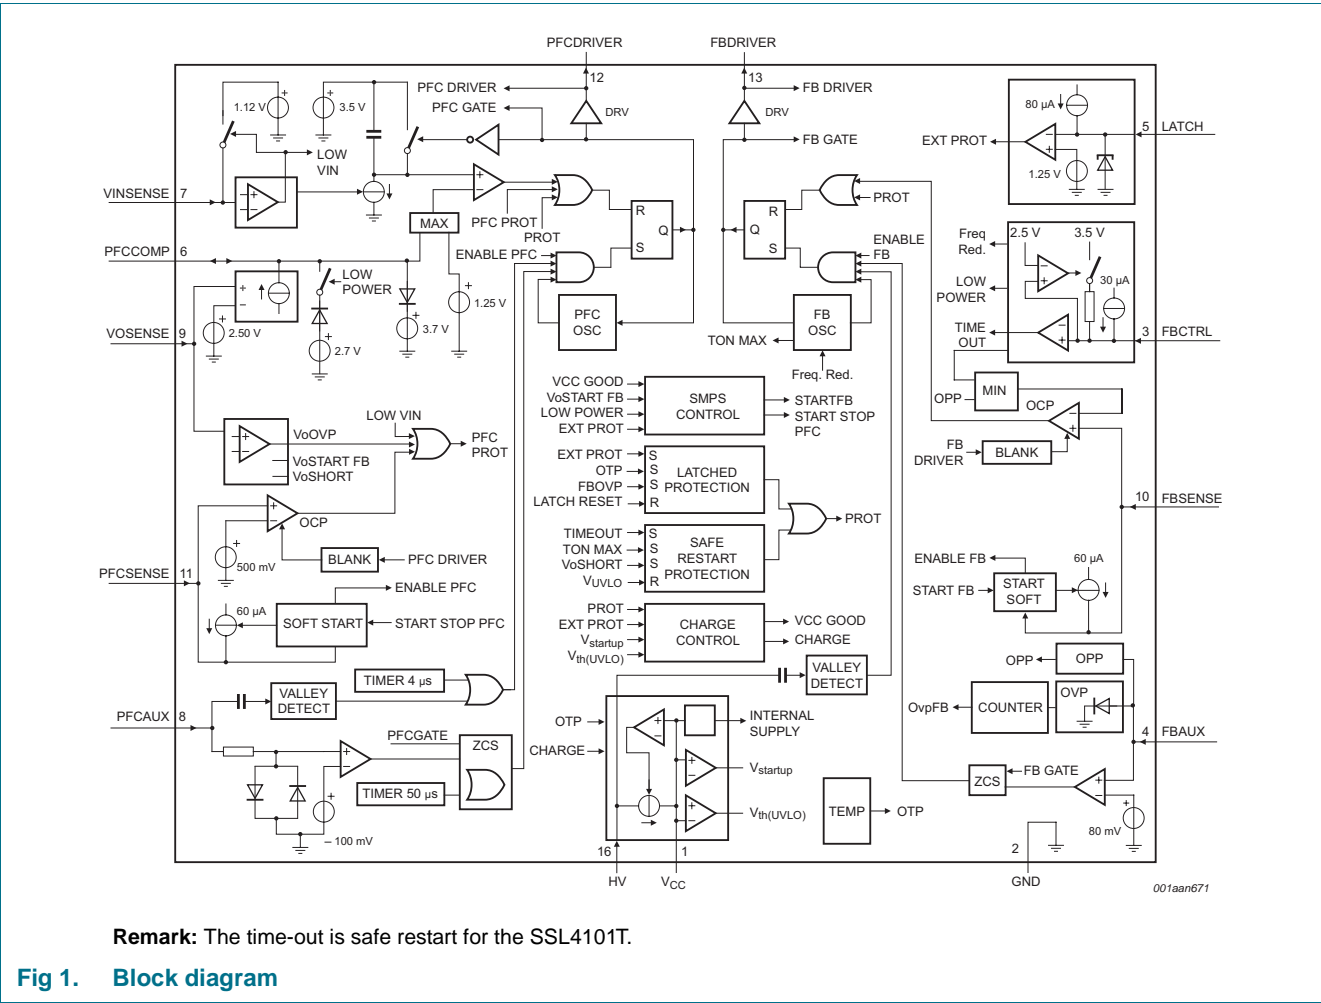

- The device can be used in all LED lighting applications that require a very efficient, low THD, high PF, true universal input voltage and cost-effective power supply solution between 10 W and 300 W.

4. Ordering information

6.2 Pin description

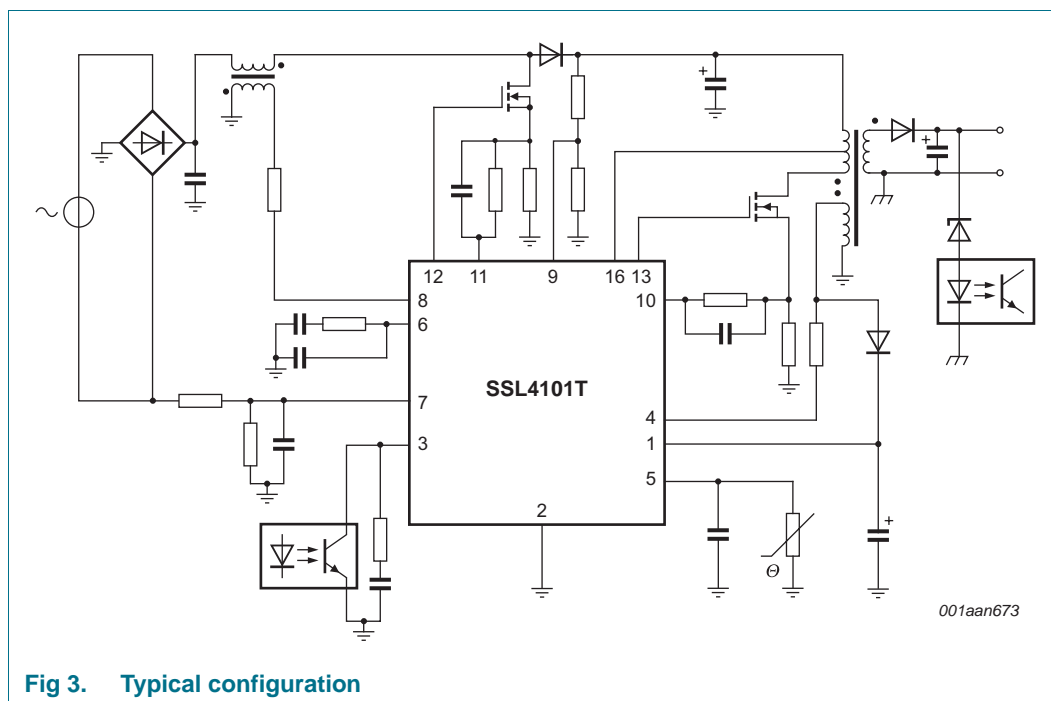

Table 2. Pin description

Symbol	Pin	Description
V _{CC}	1	supply voltage
GND	2	ground
FBCTRL	3	control input for flyback
FBAUX	4	input from auxiliary winding for demagnetization timing and overvoltage protection for flyback
LATCH	5	general purpose protection input
PFCCOMP	6	frequency compensation pin for PFC
VINSENSE	7	sense input for mains voltage
PFCAUX	8	input from auxiliary winding for demagnetization timing for PFC
VOSENSE	9	sense input for PFC output voltage
FBSENSE	10	programmable current sense input for flyback
PFCSENSE	11	programmable current sense input for PFC
PFCDRIVER	12	gate driver output for PFC
FBDRIVER	13	gate driver output for flyback
HVS	14, 15	high voltage safety spacer, not connected
HV	16	high voltage start-up and valley sensing of flyback part

7. Functional description

7.1 General control

The SSL4101T contains a controller for a power factor correction circuit as well as a controller for a flyback circuit. A typical configuration is shown in [Figure 3](#).

7.1.1 Start-up and UnderVoltage LockOut (UVLO)

Initially the capacitor on the V_{CC} pin is charged from the high voltage mains via the HV pin.

As long as V_{CC} is below V_{trip} , the charge current is low. This protects the IC if the V_{CC} pin is shorted to ground. For a short start-up time the charge current above V_{trip} is increased until V_{CC} reaches $V_{th(UVLO)}$. If V_{CC} is between $V_{th(UVLO)}$ and $V_{startup}$, the charge current is low again, ensuring a low duty cycle during fault conditions.

The control logic activates the internal circuitry and switches off the HV charge current when the voltage on pin V_{CC} passes the $V_{startup}$ level. First, the LATCH pin current source is activated and the soft start capacitors on the PFCSENSE and FBSSENSE pins are charged. When the LATCH pin voltage exceeds the $V_{en(LATCH)}$ voltage and the soft start capacitor on the PFCSENSE pin is charged, the PFC circuit is activated. Also the flyback converter is activated (providing the soft start capacitor on the FBSSENSE pin is charged). The output voltage of the flyback converter is then regulated to its nominal output voltage. The IC supply is taken over by the auxiliary winding of the flyback converter. See [Figure 4](#).

If during start-up the LATCH pin does not reach the $V_{en(LATCH)}$ level before V_{CC} reaches $V_{th(UVLO)}$, the LATCH pin output is deactivated and the charge current is switched on again.

As soon as the flyback converter is started, the voltage on the FBCTRL pin is monitored. If the output voltage of the flyback converter does not reach its intended regulation level in a predefined time, the voltage on the FBCTRL pin reaches the $V_{to(FBCTRL)}$ level and an error is assumed. The SSL4101T then initiates a safe restart.

When one of the protection functions is activated, both converters stop switching and the V_{CC} voltage drops to $V_{th(UVLO)}$. A latched protection recharges the capacitor C_{VCC} via the HV pin, but does not restart the converters. For a safe restart protection, the capacitor is recharged via the HV pin and the device restarts (see block diagram, [Figure 1](#)).

In the event of an overvoltage protection of the PFC circuit, $V_{VOSENSE} > V_{ovp(VOSENSE)}$, only the PFC controller stops switching until the VOSENSE pin voltage drops below $V_{ovp(VOSENSE)}$ again. Also, if a mains undervoltage is detected $V_{VINSENSE} < V_{stop(VINSENSE)}$, only the PFC controller stops switching until $V_{VINSENSE} > V_{start(VINSENSE)}$ again.

When the voltage on pin V_{CC} drops below the undervoltage lockout level, both controllers stop switching and reenter the safe restart mode. In the safe restart mode the driver outputs are disabled and the V_{CC} pin voltage is recharged via the HV pin.

7.1.2 Supply management

All internal reference voltages are derived from a temperature compensated and trimmed on-chip band gap circuit. Internal reference currents are derived from a temperature compensated and trimmed on-chip current reference circuit.

7.1.3 Latch input

Pin LATCH is a general purpose input pin, which can be used to switch off both converters. The pin sources a current $I_{O(LATCH)}$ (80 μ A typical). Switching off both converters is stopped as soon as the voltage on this pin drops below 1.25 V.

At initial start-up the switching is inhibited until the capacitor on the LATCH pin is charged above 1.35 V (typical). No internal filtering is done on this pin. An internal Zener clamp of 2.9 V (typical) protects this pin from excessive voltages.

7.1.4 Fast latch reset

In a typical application the mains can be interrupted briefly to reset the latched protection. The PFC bus capacitor, C_{bus} , does not have to discharge for this latched protection to reset.

Typically the PFC bus capacitor, C_{bus} , has to discharge for the V_{CC} to drop to this reset level. When the latched protection is set, the clamping circuit of the VINSENSE circuit is disabled. (see also [Section 7.2.8](#)) As soon as the VINSENSE voltage drops below 750 mV (typical) and after that is raised to 870 mV (typical), the latched protection is reset.

The latched protection is also reset by removing both the voltage on pin V_{CC} and on pin HV.

7.1.5 Overtemperature protection

An accurate internal temperature protection is provided in the circuit. When the junction temperature exceeds the thermal shutdown temperature, the IC stops switching. As long as OTP is active, the capacitor C_{VCC} is not recharged from the HV mains. The OTP circuit is supplied from the HV pin if the V_{CC} supply voltage is not sufficient.

OTP is a latched protection. It can be reset by removing both the voltage on pin V_{CC} and on pin HV or by the fast latch reset function. (See [Section 7.1.4](#))

7.2 Power factor correction circuit

The power factor correction circuit operates in quasi-resonant or discontinuous conduction mode with valley switching. The next primary stroke is only started when the previous secondary stroke has ended and the voltage across the PFC MOSFET has reached a minimum value. The voltage on the PFCAUX pin is used to detect transformer demagnetization and the minimum voltage across the external PFC MOSFET switch.

7.2.1 t_{on} control

The power factor correction circuit is operated in t_{on} control. The resulting mains harmonic reduction of a typical application is well within the class-D requirements.

7.2.2 Valley switching and demagnetization (PFCAUX pin)

The PFC MOSFET is switched on after the transformer is demagnetized. Internal circuitry connected to the PFCAUX pin detects the end of the secondary stroke. It also detects the voltage across the PFC MOSFET. The next stroke is started when the voltage across the PFC MOSFET is at its minimum in order to reduce switching losses and ElectroMagnetic Interference (EMI) (valley switching).

If no demagnetization signal is detected on the PFCAUX pin, the controller generates a zero current signal (ZCS), 50 μ s (typical) after the last PFCGATE signal.

If no valley signal is detected on the PFCAUX pin, the controller generates a valley signal 4 μ s (typical) after demagnetization was detected.

To protect the internal circuitry during lightning events, for example, it is advisable to add a 5 k Ω series resistor to this pin. To prevent incorrect switching due to external disturbance, the resistor should be placed close to the IC on the printed-circuit board.

7.2.3 Frequency limitation

To optimize the transformer and minimize switching losses, the switching frequency is limited to $f_{sw(PFC)max}$. If the frequency for quasi-resonant operation is above the $f_{sw(PFC)max}$ limit, the system switches over to discontinuous conduction mode. Also here, the PFC MOSFET is only switched on at a minimum voltage across the switch (valley switching).

7.2.4 Mains voltage compensation (VINSENSE pin)

The mathematical equation for the transfer function of a power factor corrector contains the square of the mains input voltage. In a typical application this results in a low bandwidth for low mains input voltages, while at high mains input voltages the Mains Harmonic Reduction (MHR) requirements may be hard to meet.

To compensate for the mains input voltage influence, the SSL4101T contains a correction circuit. Via the VINSENSE pin the average input voltage is measured and the information is fed to an internal compensation circuit. With this compensation it is possible to keep the regulation loop bandwidth constant over the full mains input range, yielding a fast transient response on load steps, while still complying with class-D MHR requirements.

In a typical application, the bandwidth of the regulation loop is set by a resistor and two capacitors on the PFCCOMP pin.

7.2.5 Soft start-up (pin PFCSENSE)

To prevent audible transformer noise at start-up or during hiccup, the transformer peak current, I_{DM} , is increased slowly by the soft start function. This can be achieved by inserting R_{SS1} and C_{SS1} between pin PFCSENSE and current sense resistor R_{SENSE1} . An internal current source charges the capacitor to $V_{PFCSENSE} = I_{start(soft)PFC} \times R_{SS1}$. The voltage is limited to $V_{start(soft)PFC}$.

The start level and the time constant of the increasing primary current level can be adjusted externally by changing the values of R_{SS1} and C_{SS1} .

$$\tau_{softstart} = 3 \times R_{SS1} \times C_{SS1}$$

The charging current $I_{start(soft)PFC}$ flows as long as the voltage on pin PFCSENSE is below 0.5 V (typ). If the voltage on pin PFCSENSE exceeds 0.5 V, the soft start current source starts limiting current $I_{start(soft)PFC}$. As soon as the PFC starts switching, the $I_{start(soft)PFC}$ current source is switched off; see [Figure 5](#).

7.2.6 Low power mode

When the output power of the flyback converter (see [Section 7.3](#)) is low, the flyback converter switches over to frequency reduction mode. When frequency reduction mode is entered by the flyback controller, the power factor correction circuit is switched off to maintain high efficiency.

During low power mode operation the PFCCOMP pin is clamped to a minimal voltage of 2.7 V (typical) and a maximum voltage of 3.9 V (typical). The lower clamp voltage limits the maximum power that is delivered when the PFC is switched on again. The upper clamp voltage ensures that the PFC can return to its normal regulation point in a limited amount of time when returning from low power mode.

As soon as the flyback converter leaves the frequency reduction mode, the power factor correction circuit restores normal operation. To prevent continuous switching on and off of the PFC circuit, a small hysteresis is build in, (60 mV (typical) on the FBCTRL pin).

7.2.7 Overcurrent protection (PFCSENSE pin)

The maximum peak current is limited cycle-by-cycle by sensing the voltage across an external sense resistor, R_{SENSE1} , on the source of the external MOSFET. The voltage is measured via the PFCSENSE pin.

7.2.8 Mains undervoltage lockout/brownout protection (VINSENSE pin)

To prevent the PFC from operating at very low mains input voltages, the voltage on the VINSENSE pin is sensed continuously. As soon as the voltage on this pin drops below the $V_{stop(VINSENSE)}$ level, switching of the PFC is stopped.

The voltage on pin VINSENSE is clamped to a minimum value, $V_{start(VINSENSE)} + \Delta V_{pu(VINSENSE)}$, for a fast restart as soon as the mains input voltage is restored after a mains dropout.

7.2.9 Overvoltage protection (VOSENSE pin)

To prevent output overvoltage during load steps and mains transients, an overvoltage protection circuit is built in.

As soon as the voltage on the VOSENSE pin exceeds the $V_{ovp(VOSENSE)}$ level, switching of the power factor correction circuit is inhibited. Switching of the PFC recommences as soon as the VOSENSE pin voltage drops below the $V_{ovp(VOSENSE)}$ level again.

When the resistor between pin VOSENSE and ground is open, the overvoltage protection is also triggered.

7.2.10 PFC open loop protection (VOSENSE pin)

The power factor correction circuit does not start switching until the voltage on the VOSENSE pin is above the $V_{th(ol)(VOSENSE)}$ level. This protects the circuit from open loop and VOSENSE short situations.

7.2.11 Driver (PFCDRIVER pin)

The driver circuit to the gate of the power MOSFET has a current sourcing capability of typically -500 mA and a current sink capability of typically 1.2 A. This permits fast turn-on and turn-off of the power MOSFET for efficient operation.

7.3 Flyback controller

The SSL4101T includes a controller for a flyback converter. The flyback converter operates in quasi-resonant or discontinuous conduction mode with valley switching. The auxiliary winding of the flyback transformer provides demagnetization detection and powers the IC after start-up.

7.3.1 Multimode operation

The SSL4101T flyback controller can operate in several modes; see [Figure 6](#).

Fig 6. Multimode operation flyback

At high output power the converter switches to quasi-resonant mode. The next converter stroke is started after demagnetization of the transformer current. In quasi-resonant mode switching losses are minimized as the converter only switches on when the voltage across the external MOSFET is at its minimum (valley switching, see also [Section 7.3.2](#)).

To prevent high frequency operation at lower loads, the quasi-resonant operation changes to discontinuous mode operation with valley skipping in which the switching frequency is limited for EMI to $f_{sw(fb)max}$ (125 kHz typical). Again, the external MOSFET is only switched on when the voltage across the MOSFET is at its minimum.

At very low power and standby levels the frequency is controlled down by a Voltage Controlled Oscillator (VCO). The minimum frequency can be reduced to zero. During frequency reduction mode, the primary peak current is kept at a minimal level of $I_{pkmax} / 4$ to maintain a high efficiency. (I_{pkmax} is the maximum primary peak current set by the sense resistor and the maximum sense voltage.) As the primary peak current is low in frequency reduction operation ($I_{pk} = I_{pkmax} / 4$), no audible noise is noticeable at switching frequencies in the audible range. Valley switching is also active in this mode.

In frequency reduction mode the PFC controller is switched off and the flyback maximum frequency changes linearly with the control voltage on the FBCTRL pin (see [Figure 7](#)). For stable on and off switching of the PFC, the FBCTRL pin has a 50 mV (typical) hysteresis. At no load operation the switching frequency can be reduced to (almost) zero.

Fig 7. Frequency control of flyback part

7.3.2 Valley switching (HV pin)

Refer to [Figure 8](#). A new cycle starts when the external MOSFET is activated. After the on-time (determined by the FBSENSE voltage and the FBCTRL voltage), the MOSFET is switched off and the secondary stroke starts. After the secondary stroke, the drain voltage shows an oscillation with a frequency of approximately:

$$\frac{1}{(2 \times \pi \times \sqrt{L_p \times C_d})} \quad (1)$$

Where L_p is the primary self-inductance of the flyback transformer and C_d is the capacitance on the drain node.

As soon as the internal oscillator voltage is high again and the secondary stroke has ended, the circuit waits for the lowest drain voltage before starting a new primary stroke. [Figure 8](#) shows the drain voltage, valley signal, secondary stroke signal and the internal oscillator signal.

Valley switching allows high frequency operation as capacitive switching losses are reduced, see [Equation 2](#). High frequency operation makes small and cost-effective magnetics possible.

$$\left(P = \frac{1}{2} \times C_d \times V^2 \times f\right) \quad (2)$$

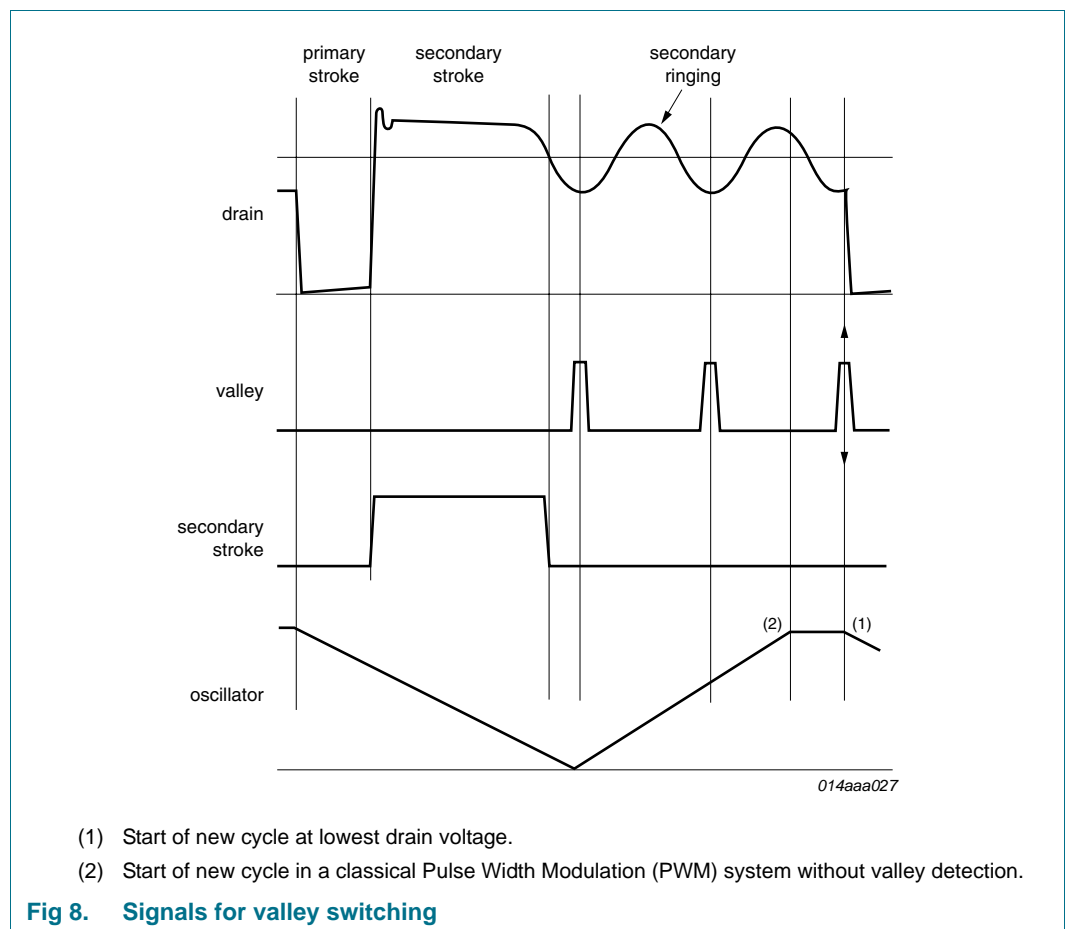

Fig 8. Signals for valley switching

7.3.3 Current mode control (FBSENSE pin)

Current mode control is used for the flyback converter for its good line regulation.

The primary current is sensed by the FBSENSE pin across an external resistor and compared with an internal control voltage. The internal control voltage is proportional to the FBCTRL pin voltage, see [Figure 9](#).

Fig 9. Peak current control of flyback part

The driver output is latched in the logic, preventing multiple switch-on.

7.3.4 Demagnetization (FBAUX pin)

The system is always in quasi-resonant or discontinuous conduction mode. The internal oscillator does not start a new primary stroke until the previous secondary stroke has ended.

Demagnetization features a cycle-by-cycle output short circuit protection by immediately lowering the frequency (longer off-time), thereby reducing the power level.

Demagnetization recognition is suppressed during the first $t_{sup(xfmr_ring)}$ time (2 μ s typical). This suppression may be necessary at low output voltages and at start-up and in applications where the transformer has a large leakage inductance.

If pin FBAUX is open circuit or not connected, a fault condition is assumed and the converter stops operating immediately. Operation restarts as soon as the fault condition is removed.

7.3.5 Flyback control/time-out (FBCTRL pin)

The pin FBCTRL is connected to an internal voltage source of 3.5 V via an internal resistor (typical resistance is 3 k Ω). As soon as the voltage on this pin is above 2.5 V (typical), this connection is disabled. Above 2.5 V the pin is biased with a small current. When the voltage on this pin rises above 4.5 V (typical), a fault is assumed and switching is inhibited. In the SSL4101T, a restart will then be made.

When a small capacitor is connected to this pin, a time-out function can be created to protect against an open control loop situation. (see [Figure 10](#) and [Figure 11](#)) The time-out function can be disabled by connecting a resistor (100 k Ω) to ground on the FBCTRL pin.

If the pin is shorted to ground, switching of the flyback controller is inhibited.

In normal operating conditions, when the converter is regulating the output voltage, the voltage on the FBCTRL pin is between 1.4 V and 2.0 V (typical values) from minimum to maximum output power.

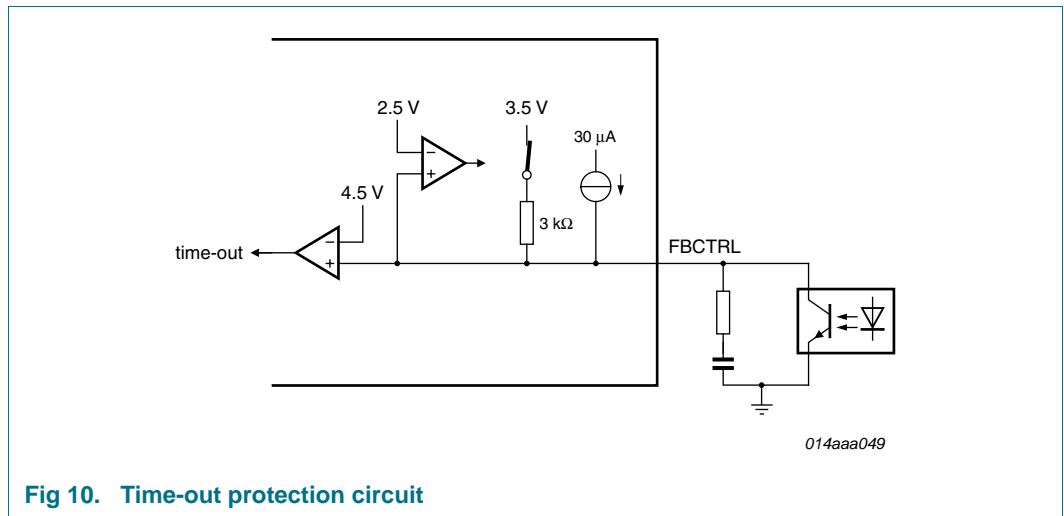

Fig 10. Time-out protection circuit

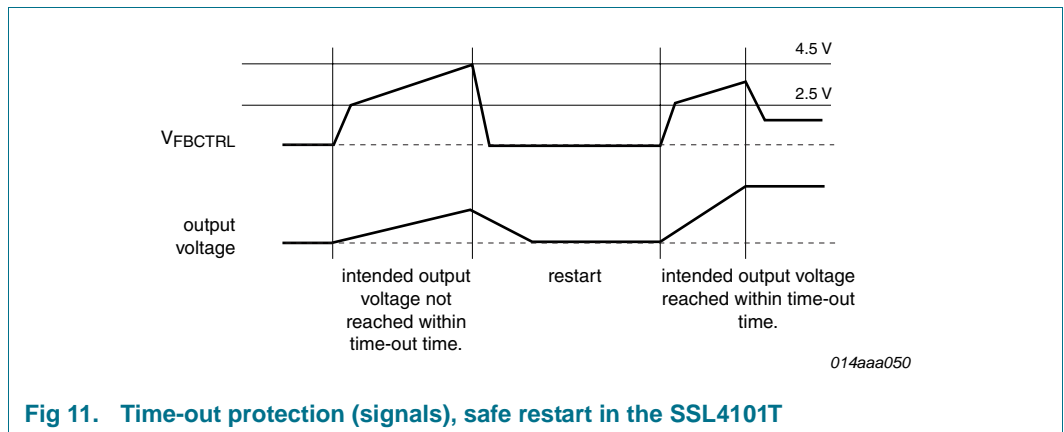

Fig 11. Time-out protection (signals), safe restart in the SSL4101T

7.3.6 Soft start-up (FBSENSE pin)

To prevent audible transformer noise during start-up, the transformer peak current, I_{DM} is slowly increased by the soft start function. This can be achieved by inserting a resistor and a capacitor between pin 10, FBSENSE, and the current sense resistor.

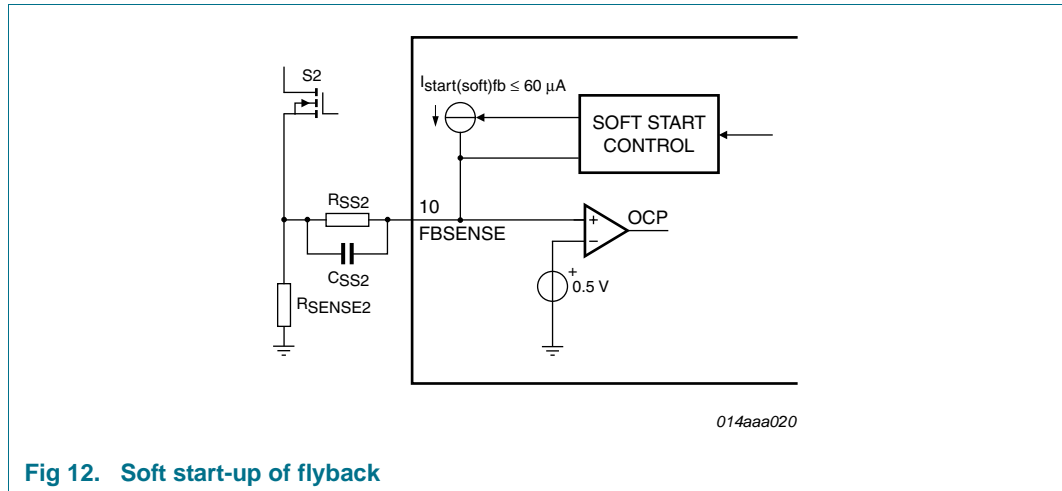

An internal current source charges the capacitor to $V = I_{start(soft)fb} \times R_{SS2}$, with a maximum of approximately 0.5 V.

The start level and the time constant of the increasing primary current level can be adjusted externally by changing the values of R_{SS2} and C_{SS2} .

$$\tau_{softstart} = 3 \times R_{SS2} \times C_{SS2}$$

The soft start current $I_{start(soft)fb}$ is switched on as soon as V_{CC} reaches $V_{startup}$. When the voltage on pin FBSENSE has reached 0.5 V, the flyback converter starts switching.

The charging current $I_{start(soft)(PFC)}$ flows as long as the voltage on pin FBSENSE is below approximately 0.5 V. If the voltage on pin FBSENSE exceeds 0.5 V, the soft start current source starts limiting the current. After the flyback converter has started, the soft start current source is switched off.

7.3.7 Maximum on-time

The flyback controller limits the 'on-time' of the external MOSFET to 40 μs (typical). When the 'on-time' is longer than 40 μs, the IC stops switching and enters the safe restart mode.

7.3.8 Overvoltage protection (FBAUX pin)

An output overvoltage protection is implemented in the GreenChip III+ series. This works for the SSL4101T by sensing the auxiliary voltage via the current flowing into pin FBAUX during the secondary stroke. The auxiliary winding voltage is a well-defined replica of the output voltage. Voltage spikes are averaged by an internal filter.

If the output voltage exceeds the OVP trip level, an internal counter starts counting subsequent OVP events. The counter has been added to prevent incorrect OVP detection which might occur during ESD or lightning events. If the output voltage exceeds the OVP trip level a few times and not again in a subsequent cycle, the internal counter counts down at twice the speed it uses when counting up.

However, when typically eight cycles of subsequent OVP events are detected, the IC assumes a true OVP and the OVP circuit switches the power MOSFET off. As the protection is latched, the converter only restarts after the internal latch is reset. In a typical application the mains should be interrupted to reset the internal latch.

The output voltage $V_{O(OVP)}$ at which the OVP function trips, can be set by the demagnetization resistor, R_{FBAUX} :

$$V_{O(ovp)} = \frac{N_s}{N_{aux}} (I_{ovp(FBAUX)} \times R_{FBAUX} + V_{clamp(FBAUX)})$$

where N_s is the number of secondary turns and N_{aux} is the number of auxiliary turns of the transformer. Current $I_{ovp(FBAUX)}$ is internally trimmed.

The value of R_{FBAUX} can be adjusted to the turns ratio of the transformer, thus making an accurate OVP detection possible.

7.3.9 Overcurrent protection (FBSENSE pin)

The primary peak current in the transformer is measured accurately cycle-by-cycle using the external sense resistor R_{sense2} . The OCP circuit limits the voltage on pin FBSENSE to an internal level (see also [Section 7.3.3](#)). The OCP detection is suppressed during the leading edge blanking period, t_{leb} , to prevent false triggering caused by switch-on spikes.

Fig 13. OCP leading edge blanking

7.3.10 Overpower protection

During the primary stroke of the flyback converter the input voltage of the flyback converter is measured by sensing the current that is drawn from the pin FBAUX.

The current information is used to adjust the peak drain current of the flyback converter, which is measured via pin FBSENSE. The internal compensation is such that an almost input voltage independent maximum output power can be realized.

The OPP curve is given in [Figure 14](#).

Fig 14. Overpower protection curve

7.3.11 Driver (FBDRIVER pin)

The driver circuit to the gate of the external power MOSFET has a current sourcing capability of typically -500 mA and a current sink capability of typically 1.2 A. This permits fast turn-on and turn-off of the power MOSFET for efficient operation.

8. Limiting values

Table 3. Limiting values

In accordance with the Absolute Maximum Rating System (IEC 60134).

Symbol	Parameter	Conditions	Min	Max	Unit
Voltages

- [1] For a typical application with a compensation network on pin PFCCOMP, such as the example shown in [Figure 3](#).
- [2] Minimum required voltage change time for valley recognition on pin PFCAUX.
- [3] Minimum time required between demagnetization detection and $\Delta V/\Delta t = 0$ on pin PFCAUX.
- [4] Hysteresis for PFC on/off control.
- [5] Guaranteed by design.

11. Application information

A power supply with the SSL4101T consists of a power factor correction circuit followed by a flyback converter. See [Figure 14](#).

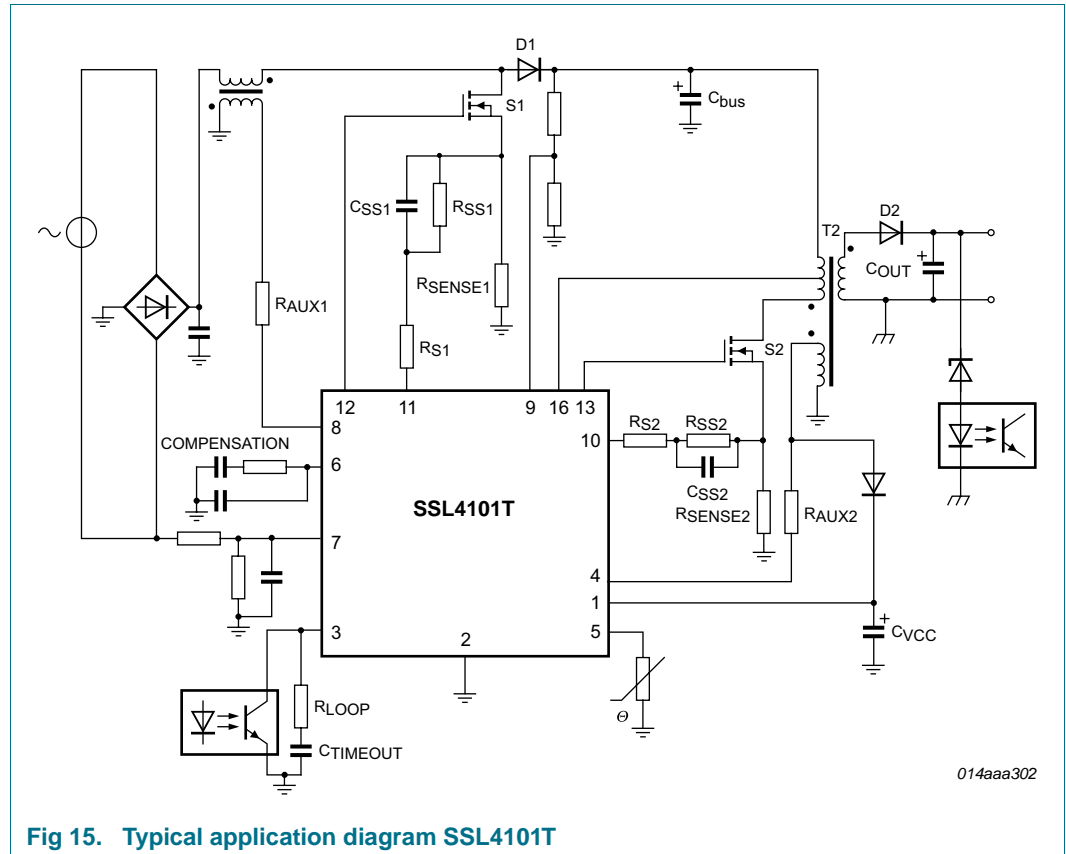

Capacitor C_{VCC} buffers the IC supply voltage, which is powered via the high voltage rectified mains during start-up and via the auxiliary winding of the flyback converter during operation. Sense resistors R_{SENSE1} and R_{SENSE2} convert the current through the MOSFETs S1 and S2 into a voltage at pins PFCSENSE and FBSENSE. The values of R_{SENSE1} and R_{SENSE2} define the maximum primary peak current in MOSFETs S1 and S2. In the example given, the LATCH pin is connected to a Negative Temperature Coefficient (NTC) resistor. When the resistance drops below [Equation 3](#) (typ), the protection is activated.

$$\frac{V_{prot(LATCH)}}{I_{O(LATCH)}} = 15.6 \text{ k}\Omega \quad (3)$$

A capacitor $C_{TIMEOUT}$ is connected to the FBCTRL pin. For a 120 nF capacitor, typically after 10 ms the time-out protection is activated. R_{LOOP} is added so that the time-out capacitor does not interfere with the normal regulation loop.

R_{S1} and R_{S2} are added to prevent the soft start capacitors from being charged during normal operation due to negative voltage spikes across the sense resistors.

Resistor R_{AUX1} is added to protect the IC from damage during lightning events.
